FOREWORD

Under Contract DAHC-04-69-C-0056 between IIT Research Institute (IITRI) and the U. S. Army Research Office-Durham, IITRI is performing a study of fragmentation hazards to unprotected personnel. This is the final report of the study which was carried out during the period July 1971 to December 1971.

The work was conducted for the Department of Defense Explosives Safety Board and supervised by Col. W. Cameron III, Chairman, Lt. Col. J. D. Coder, Project Manager, Dr. T. A. Zaker, Explosives Scientist and Mr. R. G. Perkins, Safety Engineer. Principal contributors to the presently reported work include L. A. C. Barbarek, D. I. Feinstein, H. H. Nagaoka, J. D. Rouse and J. R. Wingfield. Special acknowledgement is made to Dr. Zaker for providing trajectory algorithms and overall technical direction to this study.

Respectfully submitted, IIT RESEARCH INSTITUTE

fragment hazards. This information includes the fragment density at any point from an accidental detonation and the probability of injury to per sonnel within the hazardous area.

Published munition effectiveness data have been modified, utilizing statistical techniques, to emphasize a conservative approach, with respect to safety, by a better resolution of heavier fragments. The modi fied munition effectiveness data, which is input to the computer program have been included as a technical data appendix.

Computed results have been obtained for seven munitions and are presented in the form of contours of constant fragment density and damage probability in the horizontal plane surrounding the munition of interest. In addition, these contours have been simplified to yield an average value of the hazard as a function of range from the accidental explosion.

ABSTRACT

A computer program has been developed and documented that generates the information necessary to establish minimum separation distances between various munition types and personnel in order to mitigate fragment hazards. This information includes the fragment density at any point from an accidental detonation and the probability of injury to personnel within the hazardous area.

Published munition effectiveness data have been modified, utilizing statistical techniques, to emphasize a conservative approach, with respect to safety, by a better resolution of heavier fragments. The modified munition effectiveness data, which is input to the computer program, have been included as a technical data appendix.

Computed results have been obtained for seven munitions and are presented in the form of contours of constant fragment density and damage probability in the horizontal plane surrounding the munition of interest. In addition, these contours have been simplified to yield an average value of the hazard as a function of range from the accidental explosion.

FRAGMENTATION HAZARDS TO UNPROTECTED PERSONNEL

1. INTRODUCTION

Existing quantity-distance standards for the manufacture, handling, and storage of munitions are based on the net weight of explosive filler contained in the devices in an unsubdivided magazine, or operating building unit. Safe distances are prescribed in tabular form essentially proportional to the cube root of the explosive weight.

Because peak blast pressures from explosions of different yield are the same at distances scaled by the cube root of the respective explosive weights, existing standards imply that the acceptable risk to a given target is based on a peak blast overpressure criterion alone. On the other hand, the field of fragments projected to the far field from accidental explosion of a munition store, consisting of inert munition component fragments and secondary fragments from any enclosure, does not satisfy the same similarity rules as does the airblast. Thus, defining an acceptable blast overpressure level at a target implies the acceptance of different levels of risk of damage by fragments, depending on the quantity and composition of the munition store and its enclosure.

To develop quantity-distance standards based on consistent blast and fragment hazard levels requires determination of the damage risk due to fragments from accidental explosions as a function of the quantity and type of munitions, and of the characteristics of the source environment and the vulnerability of the target. A previous report (Ref. 1), was a first attempt aimed at applying engineering analysis, supplementary experimental efforts, and currently available data on fragmentation and damage criteria to the problem of estimating fragment hazards at explosives manufacturing and storage sites. While that report resulted in a fragment hazard model and a set of fragment density and damage probability maps for a variety of weapons and targets, this report is concerned with:

 $^{^{\}mathtt{x}}$ References listed at the end of the text.

- (1) Refining that model and making its corresponding computer algorithm usable by personnel moderately experienced at ballistic calculations,
- (2) Revising near-field fragment mass distributions to more accurately reflect their use as input in estimating fragment hazards,
- (3) Developing a new set of fragment density and damage probability maps; studying the effect of specific personnel protection criteria for unprotected personnel, and
- (4) Developing simplified two-dimensional relationships of fragment density and damage probability as a function of range.

1.1 Problem Background

Under Contract No. DAHC-04-69-C-0056 with the U.S. Army Research Office-Durham, IITRI has been conducting a series of investigations concerning fragment hazards associated with accidental detonation of munitions. This work has been performed under the direction of the Department of Defense Explosive Safety Board.

Phase I of this study was concerned with establishing quantitative damage criteria in terms of fragment mass, velocity, and attack angle for various targets including standing personnel, vehicles, aircraft, buildings and open weapon stores. In Phase II an analytical model was developed to predict the density of fragments and the probability of damage to the targets considered in Phase I from explosion of individual munitions of various types. These included gun projectiles ¿... general-purpose bombs. Here damage probability contcurs were obtained in polar coordinates for a horizontal orientation of the munition axis in each case. Phase III attempted to extend the fragment hazard model for individual munitions to the case of multiple munitions in open stores (Ref. 2). The result was a limited demonstration that an analytic model could be developed to describe the initial fragment field of a stack of munitions. However, it was also brought out that this initial fragment field was often related to munition case design, stack configuration and mode of initiation.

1.2 Program Objectives

In the current research activity the intent has been to develop an analytic tool, usable by personnel moderately experienced at ballistic calculations, and capable of generating the information necessary to establish the minimum separation distance to personnel. The objectives of the study were:

- (1) To develop and document a computer algorithm which uses munition effectiveness tables as input and computes fragment densities and damage probabilities to unprotected personnel based upon the following criteria:
 - A hazardous fragment has a kinetic energy of 58 ft-lbs or greater, and
 - An acceptable density of hazardous fragments is not more than one per 600 sq ft.
- (2) To develop a rational scheme for revising published munition effectiveness data to more accurately reflect its use as input in estimating fragment hazards.
- (3) To develop a simplified means of relating fragment density and damage probability to a radial distance over a fixed sector of the ground plane.
- (4) To utilize the computer algorithm and the revised data in order to compute the fragment density and damage probability from the explosion of a single round of each of the following seven munitions:
 - 500 1b low drag bomb Mark 32 Mod 1 (H-6 load)
 - 750 1b Bomb M117A2 (Tritional Load)
 - 105mm Howitzer Shell Ml (Composition B Load)
 - 155mm Howitzer Shell M107 (Composition B Load)
 - 175mm Gun Shell M437A2 (Composition B Load)
 - 5"/38 Projectile Mark 49 (CCMP A-3 Load)
 - 8"/55 Projectile Mark 25 (Explosive D Load)

1.3 Program Accomplishments

The major result of this study has been the development and documentation of a computer algorithm which will allow safety personnel, moderately experienced at ballistic calculations, to make the computations necessary to establish separation distances for personnel due to fragment hazards. A rational statistical scheme has also been developed and demonstrated which revises published munition effectiveness data to more conservatively reflect its use in estimating fragment hazards. A set of computations were made for seven munitions and the results are presented as contour maps of total fragment number densities, damaging fragment number densities and injury probabilities. The contour maps have also been simplified to yield curves of number density and injury probability as a function of radial distance from the munition source within a constant sector of the ground plane. (i.e., the nose, base and sidespray sectors) These results serve both to demonstrate the capability of the computer algorithm and also as design aids for explosive safety personnel.

1.4 Program Highlights

The following sections of this report are organized in such a way as to first present the analysis on which the fragment hazard computer model is based, to next present an analysis of the munition effectiveness data which is input to that computer model and to finally summarize the study in the form of conclusions reached and recommendations as to model improvement.

Appendices, covering the study's deliverable items, are included following the conclusion of the report. These appendices include a user manual for operation of the fragment hazard computer program, a listing of the computer program, the contours and simplified curves describing the fragment hazard associated with unprotected personnel exposed to these

seven munitions. The revised munition effectiveness data for the seven munitions were published as a separate classified document.

2. THE FRAGMENT HAZARD MODEL

This section describes the analysis which forms the basis for the computational model for predicting fragment density and injury probability contours for various munitions. The mathematical model, illustrated in Fig. 1, is limited to the consideration of the single munition without environmenta protection. The model has been programmed for digital computation, is modular and accepts as inputs:

- (1) The spatial distribution of fragment masses and velocities for single munitions, which are defined for intervals of polar angle. (i.e., munition effectiveness tables)
- (2) The k-factors for the individual munitions, which express the relationship between fragment masses and projected areas for various munition types.
- (3) Vulnerability criteria for targets of interest. (e.g., kinetic energy and critical densities)

Output of the model includes:

- (1) Fragment density contours showing distances to isodensity lines for all azimuths. Contours can be printed for all fragments or for various classes of fragments.
- (2) Injury/damage probability contours, showing ground distances to isoprobability curves at all azimuths for various munition/target combinations.

Elements of this model include the following steps:

(1) Munition performance data is converted to an internal form. All data is normalized into a a common internal form, wherein the average fragment velocity and the average mass and number density for each of several fragment mass categories are represented as tabular functions defined everywhere on the surface of a sphere of unit radius located at the origin. Gaps in the original data are filled in, and in addition the data may be smoothed if this seems desirable.

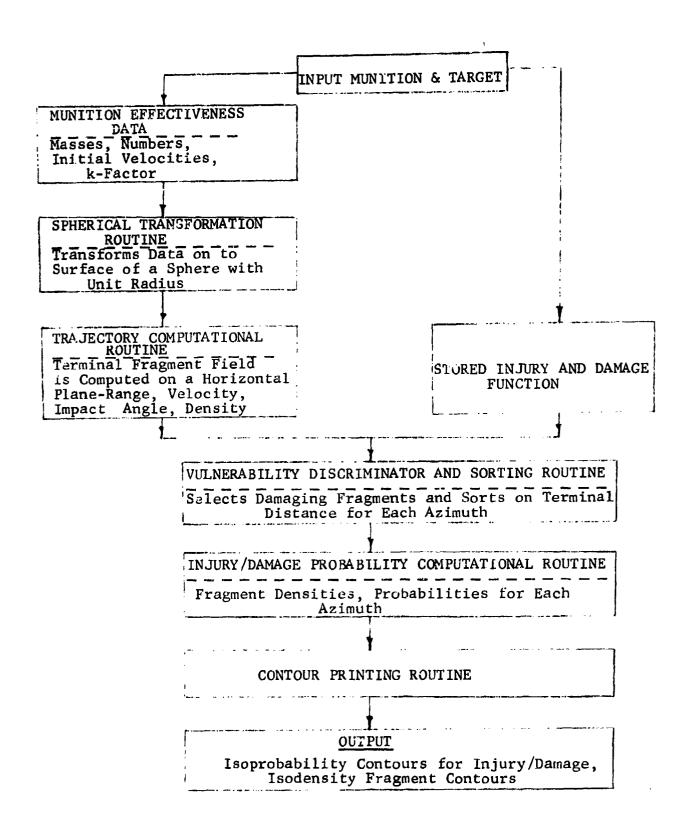

Fig. 1 FLOW CHART FRAGMENT HAZARD MODEL

- (2) A terminal fragment field is computed on a selected horizontal plane (i.e., the plane is above, below or passing through the origin) utilizing routines for evaluating fragment trajectories. The quantities computed for each mass category are impact velocity, impact angle and number of fragments per sq ft in a plane normal to the impact angle. These quantities are expressed as tabular functions of range and azimuth for output processing.
- (3) Selected functions of the fragment field quantities computed in step 2 are computed and plotted in this step. A wide range of functions are available. The basic functions involve the fragment field alone, and do not consider characteristics of a target. Examples of these functions are number of fragments per sq ft, and total fragment kinetic energy per sq ft.

The target functions use target characteristics to determine the number of damaging fragments and te probability of damage at every point in the field. These functions use tables or formulas to determine whether or not a fragment is damaging, by finding the minimum velocity required by that fragment to damage the target. The fragment is considered to be damaging if its velocity exceeds the threshold.

(4) Fragment field functions may be plotted either on the printer, or on an off-line plotter if the output tape is run through an appropriate post-processor.

2.1 <u>Trajectory Analysis</u>

Large quantities of terminal ballistic property data are used in developing the outputs of the computational model described above. These data are generated from the equations of motion for the fragments. Since these computations represent the bulk of the computational burden involved in exercising the model and their accurate evaluation is essential, it is desirable to utilize a highly efficient numerical procedure for calculating trajectories.

Figure 2 illustrates the motion of a fragment moving under the influence of aerodynamic drag and gravity forces in nonrotating local coordinates \overline{x} , \overline{y} tangent and normal to the trajectory. The corresponding equations of motion are:

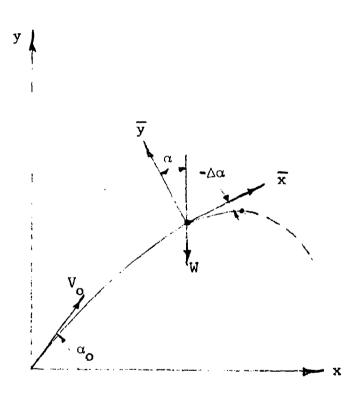

Fig. 2 COORDINATE SYSTEMS AND TRAJECTORY GEOMETRY

$$\frac{\mathbf{x}}{\mathbf{x}} + \beta \mathbf{v} \, \, \frac{\mathbf{x}}{\mathbf{x}} + \mathbf{g} \, \sin \alpha = 0 \tag{1}$$

$$\frac{\ddot{y}}{y} + \beta v \dot{y} + g \cos \alpha = 0$$
 (2)

where dots denote differentiation with respect to time t. In these equations, g is the acceleration of gravity, v is the speed in the path, and α is the angle between the \overline{x} - axis and the horizontal. Instantaneously we have \overline{x} = v and \overline{y} = 0.

The aerodynamic coefficient β is given by

$$_{i} = C_{D} w A/2W$$
 (3)

where $\mathbf{C}_{\mathbf{D}}$ is the drag coefficient, w is the specific weight of air, A is the cross-sectional area of the fragment normal to the flight direction, and W is the fragment weight. The fragment area and weight are related empirically (Ref. 3) through a ballistic density k as follows

$$W = k A^{3/2} \tag{4}$$

In terms of k, the aerodynamic coefficient becomes

$$p = c_{D} w/2 (k^{2}W)^{1/3}$$
 (5)

An approximate local solution to the equations of motion is obtained by separating the displacement into two parts, one a basic solution satisfying the local initial conditions and the equations of motion with gravity absent, and the other a pair of perturbations satisfying the linearized residual equations (Ref. 4). The results, applicable for small departures of the trajectory from the local initial tangent, are equivalent to difference equations appropriate to an arbitrary time step in a numerical integration of the complete trajectory.

The displacement \overline{x} is assumed to be of the form

$$\overline{x} = \overline{x}_0 + \overline{x}_p \tag{6}$$

where the basic solution $\overline{\mathbf{x}}_{\mathbf{0}}$ satisfies

$$\frac{\infty}{\overline{x}_0} + \beta \frac{\dot{x}^2}{\overline{x}_0^2} = 0 \tag{7}$$

and the initial condition $\bar{x}_0 = v$, while the perturbation \bar{x}_p satisfies the associated residual of Eq. (1).

The drag coefficient C_D in general depends on the Mach number, and the atmospheric weight density w is a function of altitude. If both of these factors are assumed to be constant during the time interval of interest, however, the aerodynamic coefficient β is a constant and Eq. (7) is easily integrated. The results are

$$\overline{x}_0 = [\log (1+u)] / \beta$$
 (8)

$$\dot{\bar{x}}_0 = v_0/(1+u) \tag{9}$$

where

$$\mathbf{u} \equiv \beta \mathbf{v_o} \mathbf{t} \tag{10}$$

In these expressions, t is measured from the time at which the fragment is at the local coordinate origin in Fig. 1, and ${\bf v}_{\rm o}$ is the value of ${\bf v}$ at that time.

Substituting Eq. (6) and (7) into the equations of motion, expanding v in binomial series, and neglecting terms of second order and higher in $\frac{1}{x_p}$ and $\frac{1}{y}$, we reach the following results:

$$\frac{\dot{x}}{\ddot{x}_p} + 2\beta \dot{x}_o \dot{x}_p + g \sin \alpha = 0$$
 (11)

$$\frac{\mathbf{x}}{\mathbf{y}} + \beta \mathbf{x}_{0} \dot{\mathbf{y}} + \mathbf{g} \cos \alpha = 0$$
 (12)

These equations are linear in the displacement perturbations \bar{x}_p and \bar{y} , and can be integrated analytically by standard methods. The displacement and velocity perturbations are

$$\bar{x}_{p} = -(g/2) t^{2} \sin \alpha (1+u/3)/(1+u)$$
 (13)

$$\bar{y} = -(g/2) t^2 \cos\alpha [u(1+u/2) - \log(1+u)]/u^2$$
 (14)

$$\frac{1}{x_p} = -gt \sin\alpha \left[1 + u(1 + u/3) \right] / (1 + u)^2$$
 (15)

$$\frac{\dot{y}}{y} = -gt \cos \alpha (1+u/2)/(1+u)$$
 (16)

where u is defined as before by Eq. (10).

The leading factors on the right in the foregoing equations express the position and velocity changes due to gravity in the elementary case of a drag-free trajectory. The multipliers containing u all approach unity as u vanishes, and can be viewed as corrections on the effect of gravity due to drag.

The drag coefficient and atmospheric density are assumed to be constant during each time step at their values at the beginning of the step. The method is self-starting in that the position and velocity changes are computed from initial values at the current step only.

Initial values $v = V_0$ and $\alpha = \alpha_0$ are assumed to be given at the fixed coordinate origin in Fig. 2. Equations (8), (9), and (13) through (16) give directly the displacement and velocity components after a typical time step t in the local coordinates. With respect to the fixed coordinates, the displacements during the time step are obtained from the relations

$$\Delta x = \overline{x} \cos \alpha - \overline{y} \sin \alpha \tag{17}$$

$$\Delta y = \overline{x} \sin \alpha + \overline{y} \cos \alpha \tag{18}$$

while the rotation of the trajectory tangent is given by

$$in = \tan^{-1} \left(\frac{\dot{y}}{y} / \frac{\dot{x}}{x} \right) \tag{19}$$

For low register trajectories, (i.e., those launched at angles less than that corresponding to maximum range) the above analytic perturbation equations with $\alpha = \alpha_0$ furnish an approximate solution for the complete trajectory in one time step t, the total time of flight. At impact, the expressions for the position coordinates x and y are of the form:

$$x = (\bar{x}_0 + \bar{x}_p) \cos \alpha_0 - \bar{y} \sin \alpha_0$$
 (20)

$$y = (\overline{x}_0 + \overline{x}_p) \sin \alpha + \overline{y} \cos \alpha = 0$$
 (21)

where \overline{x}_0 , \overline{x}_p , and \overline{y} are given by Eq. (8), (13), and (14).

2.2 Fragment Density Computation

Munition effectiveness data are used to derive initial conditions for the ballistic trajectories of fragments. These data are in the form of initial velocity and number of fragments, in each of several mass categories, and are functions of polar angle measured from the nose of the munition. The resulting fragment density at any point of interest can be computed deterministically from the known terminal points of fragments in all the mass intervals in each polar zone.

An individual munition is regarded as a nonisotropic point source of fragments which is rotationally symmetric about its longitudinal (nose-to-base) axis. Thus, the properties of the fragments emitted by a single munition are functions of polar angle 0 measured from the nose. The format of typical munition effectiveness data (Ref. 5) is shown in Table 1. Fragments in all mass intervals are assumed to be emitted from a given polar zone at the same velocity.

A single munition is assumed to be detonated at a level ground surface, with the munition axis horizontal. In order to determine the probability of damage to targets at various distances and directions from the source, it is first necessary to calculate the number dent ties of fragments of different terminal ballistic properties in the field surrounding the source.

The fragments from a munition, considered as a point source on the ground, may be regarded as originating from positions on a hemispherical envelope enclosing the source. Each point of origin on the hemisphere defines an elevation angle α_0 and an azimuth ϕ in the horizontal plane measured from the nose of the munition.

In Fig. 3, let u, v, and w be rectangular coordinate axes centered at the source, with w the vertical direction and the nose of the munition in the positive v-direction. Let R_o be the (arbitrary) hemisphere radius, and θ be the polar angle measured from the nose of the munition.

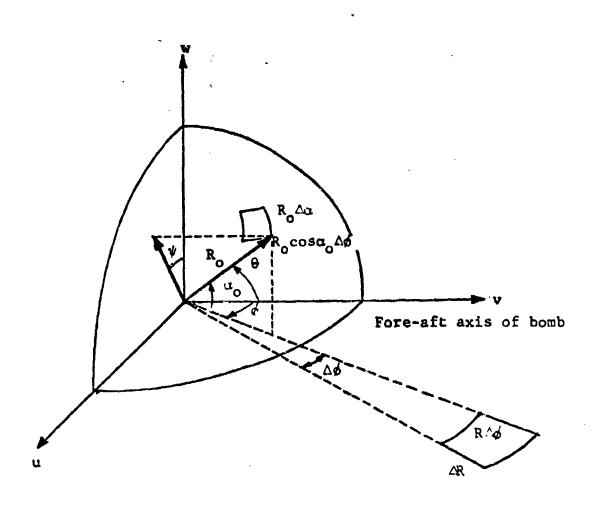

Fig. 3 FRAGMENT SOURCE GEOMETRY

Transformation formulas between the spherical coordinates $(9,\psi)$ with the munition nose at the pole and the spherical coordinates (α_0, ϕ) with the pole vertical give the following relations:

$$\cos \theta = \cos \alpha_0 \cos \phi \tag{22}$$

$$\cos \psi = \sin \alpha_0 / \sin \theta \tag{23}$$

Fragments on ballistic trajectories in the absence of wind travel in planes of constant azimuth ϕ .

For an individual munition, the initial fragment properties are functions of polar angle θ only. Therefore, for given elevation angle α_0 and azimuth ϕ , the associated polar angle can be computed from Eq. (22) and all initial fragment properties at that point on the hemisphere can be obtained from munition performance data.

Now consider the fragments of a single mass interval, all having the same average ballistic properties, emitted from a particular munition at a point (α_0, ϕ) on the enclosing hemisphere. For simplicity, consider target points in the ground plane of Fig. 3. The terminal point corresponding to this initial point on the hemisphere is uniquely determined for each mass category through the associated ballistic trajectory.

The family of trajectories for fragments of a given average mass (i.e., those in one mass interval) can be thought of as a mapping of points on the hemisphere into points on the ground plane. Fragments of one mass interval originating from an element of area $R_0^2 \cos \alpha_0 \Delta \phi \Delta \alpha_0$ on the hemisphere are projected into the element of area $R\Delta \phi \Delta R$ on the ground plane. Thus if n_1^0 is the number density of fragments in mass interval i at the source hemisphere and n_1 is the number density at the terminal point R, we have

point R, we have $n_{i} = n_{i}^{0} \frac{R_{o}^{2} \cos \alpha_{o}}{R|dR/d\alpha_{o}|}$ (24)

This formula permits computation of the number density of fragments in each mass interval originating from a point on the source hemisphere at any azimuth ϕ , since for given initial ballistic properties the terminal point R is known from trajectory calculations. To calculate the number density across a plane normal to the final trajectory, equation (24) is replaced by

$$n_{i} = n_{i}^{O} \frac{R_{o}^{2} \cos \alpha_{o}}{R \left| -\sin \alpha_{f} \frac{dR}{d\alpha_{o}} \right|}$$
 (25)

where as is the final trajectory elevation angle.

For an individual munition the mapping derivative $dR/d\alpha_{\mbox{\scriptsize o}}$ is given by

$$\frac{dR}{d\alpha_o} = \frac{\partial R}{\partial \alpha_o} + \frac{\partial R}{\partial V_o} \frac{\partial \theta}{\partial \alpha_o} \frac{dV_o}{d\theta}$$
 (26)

where V_{Ω} is the initial velocity. From Eq. (22) we have

$$\frac{\partial \theta}{\partial \alpha_0} = \sin \alpha_0 \cos \phi / \sin \theta \tag{27}$$

The partial derivatives $\partial R/\partial \alpha_0$ and $\partial R/\partial V_0$ can be obtained analytically for lower register fragments; however, for upper register fragments, they must be obtained by numerical differentiation of a precalculated ballistic file. The analytic expressions for the lower register are

$$\frac{\partial R}{\partial \alpha_0} = \frac{2R - \overline{x}_0 \cos \alpha_0}{\tan 2\alpha_0} - \frac{\overline{x}_0 \cos \alpha_0}{\sin 2\alpha_0} - \frac{2R - \overline{x}_0 \cos \alpha_0}{\tan \alpha_f}$$
(28)

$$\frac{\partial R}{\partial V_0} = -2(R - \bar{x}_0 \cos \alpha_0 + \bar{x}_0 \sin \alpha_0 / \tan \alpha_f) / V_0$$
 (29)

The derivative $dV_{0}/d\theta$ is determined from munition effectiveness data.

The computer model, moving along rays of azimuth in the horizontal plane, determines the terminal properties of lower register fragments at preselected radial increments of range

out to maximum range. At maximum range the corresponding elevation angle is noted and the remaining elevation angle up to 90 degrees is divided into equal increments. The model, utilizing the multi-step trajectory routine with a fixed drag coefficient of 1.28, calculates the terminal properties of the upper register fragments corresponding to each increment of elevation angle. The fragment number density can be determined exactly at prescribed terminal points for lower register fragments and, by interpolation, at these same points for the upper register fragments. These contributions are accumulated to give the total fragment density at the preselected radial distances. By symmetry it is only necessary to perform the analysis in half the horizontal plane to one side of the munition axis.

For a particular target, nondamaging fragments based on the applicable target vulnerability criterion are excluded from the accumulated number density. The number densities so calculated represent, in a statistical sense, expected values of the numbers of impacts per unit area. That is, these results, calculated deterministically as a function of position in the horizontal plane, are the numbers of damaging impacts per unit area to be expected on the average. To calculate the associated probability of damage (i.e., impact by one or more damaging fragments) to a particular target requires a statistical representation of the process, incorporating these expected values of fragment number density. In this study the target is a sphere of unit cross sectional area and fragments are considered to intersect this target across a plane normal to the final trajectory direction.

2.3 Target Damage Probability

Calculation of the probability of damage to a particular target requires a statistical representation of the process of impact by damaging fragments, involving the target area and the expected number of impacts per unit area. The number density of fragments is a function of position of the spherical target in the horizontal plane of interest.

Consider a target of projected area A_i normal to the trajectory of fragments of mass interval i at the associated terminal point. Let $\overline{n_i}$ be the expected number of impacts per unit area of fragments satisfying the applicable target vulnerability criterion. The impact process is assumed to be uniformly random in the immediate neighborhood of the point of interest. That is, impact by a damaging fragment is equally likely on all equal elements of area in the vicinity of the point. Statistically, we then have what is termed a Poisson process. The probability $p_i(j)$ of exactly j impacts on the target by damaging fragments of mass interval i is given by

$$p_{i}(j) = \frac{(\overline{n}_{i}A_{i})^{j} \exp(-\overline{n}_{i}A_{i})}{j!}$$
 (30)

The probability of impact by none of the damaging fragments of mass interval i is therefore

$$p_i(0) = \exp(-\overline{n}_i A_i) \tag{31}$$

The target is assumed to be damaged if struck by one or more damaging fragments of any of the mass intervals. On this basis, the probability of damage to the target, q, is given by

$$q = 1 - \exp(-\sum \overline{n}_i A_i)$$
 (32)

This last formula permits direct computation of the probability of damage to a given target at every point of the horizontal plane of interest from the accumulated number densities of damaging fragments and the associated projected areas. The target in this study was a standing man. The man was considered to present a projected area varying from 1.33 sq ft in plan to 9.0 sq ft frontal area. A₁ was then calculated as the sum of the projections of both a vertical and a horizontal target on a plane normal to the final trajectory direction. The vertical target had an area of 9.0 sq ft and the horizontal target had an area of 1.33 sq ft.

2.4 Description of Model Output

Contour maps, describing each of the seven munitions of interest, listed in Section 1.2, were produced utilizing the computer model and are included as Appendix B. For each munition there are three contour maps: one describing the fragment flux (i.e., target hits per sq ft) due to all fragments; another describing the fragment flux of all fragments with terminal energy exceeding 58 ft-lbs; and a third which presents the probability of serious injury to standing personnel computed as described in the previous section.

Another set of figures is shown in Appendix C. Here again, there are three sets of figures per munition. These are simplified curves, derived from the corresponding contour maps, and represent fragment density and damage probability in certain sectors of the ground plane as functions of radial distance only. There are three of these fixed sectors: that is, 10-degree sectors in the base and nose of the munition and a third sector representing a peak side-spray. This third sector varied somewhat among all of the munitions, but was usually defined by a line of peak values appearing within \pm 10 degrees of the 90-degree azimuth. This line of peak values did not usually include the outermost or lowest value contour. The average value of this contour in the side spray sector was determined by inspection from the maps.

Both the contours and the corresponding curves represent the fragment field from a minimum range of 250 ft out to the prescribed limit of effect (i.e., one hit per 6000 sq ft for fragment densities and a probability value of 0.0001). The minimum range is a function of a prescribed input variable and was chosen as 250 ft in this study. Since the results represent a single unit of munition and it is anticipated that future use of these results may be directed at multiple unit stacks, it seems reasonable to assume that the far fields results will be of more interest and the minimum range of 250 ft will be quite sufficient.

3. MUNITION EFFECTIVENESS DATA

Previous studies (Ref. 2) have indicated published munition effectiveness data, in their present form, are not suitable for far-field fragment hazard analysis. In general, these data place heavier fragments into one or two broad weight intervals with a corresponding average weight. Since the heavier fragments travel greater distances and their resulting terminal kinetic energy effect is high, it is necessary that these fragments be resolved into an adequate number of weight intervals.

11

1 i

This section of the report describes several tasks which were undertaken to provide a systematic approach to both illustrating the need for and subsequently the methods utilized in revising munition effectiveness tables.

3.1 Documentation of Original Fragmentation Arena Data

In collaboration with the Ballistics Research Laboratory at Aberdeen Proving Grounds, the fragmentation arena test procedure and data analysis techniques used to obtain munition effectiveness data were reviewed. Arrangements were made to examine the original arena test firing records at the APG Technical Library for the following munitions:

- 105 mm Howitzer Projectile Ml
- 155 mm Howitzer Projectile M107
- 175 mm Gun Projectile M437A2
- 750 lb General Purpose Bomb M117A2 (APG Data)

Subsequently, contacts were established at NWL to obtain similar arena test data for the following munitions.

- 5-in/38 Projectile Mark 49 Mod O (VT)
- 8 in/55 Projectile Mark 25 Mod 1 (HC)
- 500 1b Low Drag Bomb Mark 82 Mod 1
- 750 lb General Purpose Bomb M117A2 (Eglin AFB Data) For each munition the following information was documented.

• Test munition physical measurements

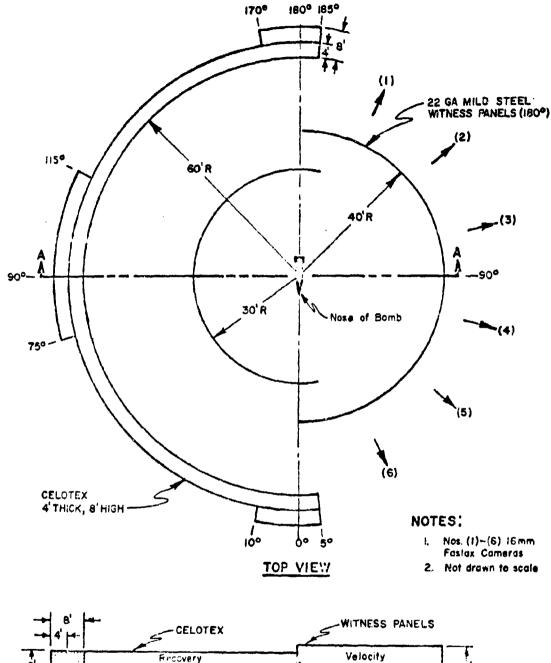

DAPPEN NO.

- Specifications for each arena test facility
- Listing of mass groups and polar zones
- Individual listing of fragment weights greater than 150 grains.

An understanding of the fragmentation arena test techniques is an important factor in the proper assessment of the larger and more hazardous fragments. The arena test is used to determine fragment mass, velocity and spatial distribution of high-explosive munitions. The munition axis of symmetry is located horizontally and is taken as the polar axis. Designating the polar angle by θ and the azimuth angle as ϕ , the fragmentation characteristics are a function of θ , and gravity effects are assumed negligible. An arena is constructed of an appropriate size as illustrated in Fig. 4. The arena test is designed to sample fragmentation characteristics in various polar angle intervals ranging between $\theta \approx 0$ degree at the nose, and $\theta = 180$ degrees at the base of the munition. These data samples are used to predict the fragmentation characteristics for the entire munition.

An important aspect of the arena test procedure is the relationship between the sample size obtained from the incremental polar zone on the arena recovery panel and the corresponding munition polar zone. Calculations were made from actual arena setup data to estimate the magnification factor associated with the integrated munitions data. These data, summarized in Table 2, indicate that only about 2 to 7 percent of the fragments are sampled in the 90 degree polar angle region (side spray) for each test. Thus, each fragment must be multiplied by a factor of 15 to 60 to obtain integrated data. It should be noted that the fragment sample size is about doubled at the 30 or 150 degree polar angle regions, and then increases rapidly to near 100 percent at 0 and 180 degrees (nose and base regions).

Table 3 summarizes data associated with fragments in excess of 150 grains for the munitions of interest. The 150 grain fragment was assumed to be the minimum damaging fragment mass projected at low elevations. Table 3 indicates that fragments in excess of 150 grains represent only 5 to 18 percent of the

% NT - Percent No. of Fragments Greater than 150 Grains

% WT - Percentage of Total Weight for Fragments Greater than 150 Grains

total number of fragments but comprise 52 to 93 percent of the total case metal weight considered. In general, the weight groups beyond 150 grains are few in number and wide in weight interval. Since these heavier fragments are few in number and averaged over wide weight intervals, the data samples developed from arena tests are statistically inadequate in describing the characteristics for these potentially damaging fragments. As an example, the munition effectiveness data may list 60 fragments in one polar zone, each weighing 1100 grains and with a common velocity, while all other zones are free from that category of fragments. As input to the hazard model, these data could yield a ring-shaped hazardous region in the far field. It may be more reasonable to assume these fragments to be distributed statistically such as 30 units at 900 grains, 20 units at 1200 grains, and 10 units at 1500 grains, with the fragments being dispersed over three polar zones. In this regard, the distribution characteristics associated with fragments less than 150 grains could be used to predict the statistical distribution characteristics for the heavier fragments.

It should be emphasized that the munitions effectiveness data are valid statistically for characterizing munition performance for fragments of interest to the user. In general, the heavier fragments are only considered in the arena test procedure to assure that a conservation of weight is maintained between the recovered fragments in the arena sample and the integrated munition effectiveness data.

3.2 Revision of Munition Effectiveness Data

Seven sets of data, corresponding to the seven munitions of interest, were considered and of these, six were altered to overcome one of the following two fundamental deficiencies:

- 1) Gaps Toward the heavier mass categories, "data voids" appeared making it difficult to approximate the cumulative distribution of mass as a continuous function.
- 2) Refinement The cumulative distribution of mass loses definition where the final mass categories are an amalgam of all mass greater than the upper limit of the preceding category.

The first of these deficiencies were more predominate in the 175 mm and 155 mm munitions while the remaining sets of data, with the exception of the 105 mm, had poor refinement in the heaviest mass category. Each problem was handled differently, and in general, the problem of refinement was the most amenable since it was not necessary to add "fictitious" mass categories as it was in the case of data with void deficiencies.

1

1

It is prudent to comment that the best improvement which can be made on the experimental data is increasing the sample size. It is recognized then that with restricted data collection techniques and limited sample sizes, extrapolation and statistical inference must be conservative and cautious.

The basic indicators which were used to establish trends and to make decisions, were the average mass (\overline{m}) per mass category, the associated standard deviation (σ) , the ratio $-\sqrt{m}$, and the average mass frequency (f) for each mass category.

The primary data for a particular munition was processed to print out a matrix of fragment weights and frequencies with mass categories as columns and polar zones as rows. Calculated information consisted of average mass $\overline{\mathbf{m}}_i$ over all polar zones j within each mass category i, the corresponding average frequency \mathbf{f}_i , the standard deviation σ_i , a ratio $\sigma_i/\overline{\mathbf{m}}_i$ for each mass category, the total weight $\mathbf{W} = \Sigma$: $\overline{\mathbf{m}}_{ij}\mathbf{f}_{ij}$, and the cumulative distribution of weight

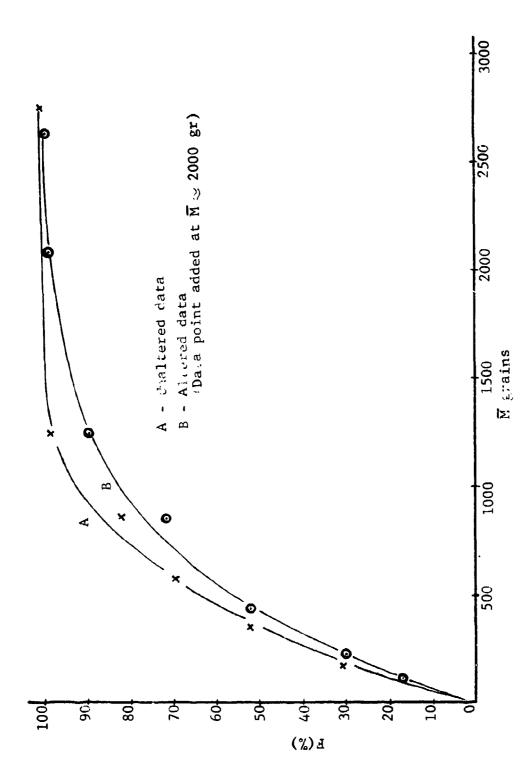

$$F_{k} = \sum_{i=1}^{k} \frac{\sum \overline{m}_{ij} f_{ij}}{W} \quad k = 1, 2 \dots N$$
 (33)

for all N mass categories. The two fundamental deficiencies noted in the data were identified by inspecting the cumulative frequency curve for obvious gaps in the domain of the function and by observing anomalies in trend of standard deviation values for the mass categories.

Two cases which will serve to illus rate the method.

A. The 155 mm Munition

The cumulative distribution curve (Fig. 5) was plotted and it was noted that although the average mass categories range up

CUMULATIVE DISTRIBUTION OF MASS FOR THE 155 MM MUNITION Fig. 5

to about 2800 grains, almost 100 percent of the weight has been accumulated at about 1200 grains. By inspection of the curve in Fig. 5 it was decided to start by adding a data point at about 2000 grains so that that portion of the curve would be less sparcely populated. The next decisions must phrase an answer to the questions: how much, and in what manner?

First and second moments were used as the indices of central measure and dispersion of the distribution of mass and frequency across the polar zones within a mass category. In general, the data available in the higher mass categories is not sufficient to construct a reasonable frequency histogram. In the lower mass categories it becomes possible to do this and in order to obtain a graphical sense for the distribution of this mass, histograms were constructed for several categories. Figure 6 depicts the weight distribution in the 200-250 category for the 155 munition. There is another distribution which will be used as a decision aid. This is the frequency of mass over all mass categories with polar zones constant. This curve is shown in Fig. 7.

Essentially then, we have a two-dimensional polar zone - mass frequency matrix in which we would like to make additional entries. Toward this end trends are identified in two directions: across columns (mass categories), and across rows (polar zones). The intersection of these trends at the point in question allows an estimate of the permissible entries which can be made at this point.

It was noted that the ratio σ_i/\overline{m}_i tended to be fairly constant and, in case of the 155 mm munition, the average ratio was on the order of .061. Using this in conjunction with the intention of adding mass at \overline{m} = 2000, the dispersion measure is

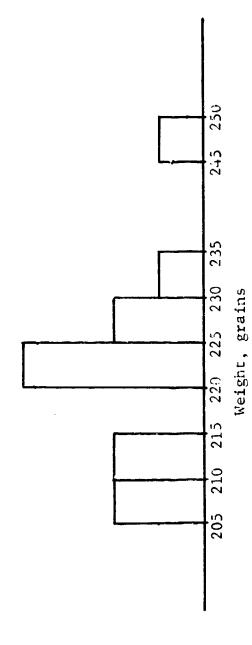

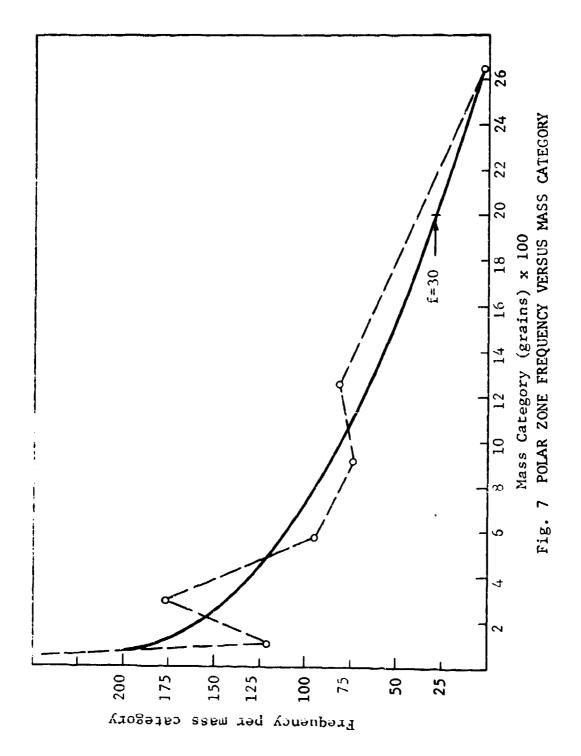

Fig. 6 DISTRIBUTION OF MASS IN THE CATECORY 200 - 250 GRAINS FOR THE 155 MM MUNITION

estimated as .061 x 2000 = 122. The plot of polar zone frequency versus mass category (Fig. 7) was consulted, and a frequency of 30 was associated with the average mass of 2000 grains. By observing the trend across the mass categories, attention focused on polar zone 7 (60-70 degrees) and polar zone 11 (100-110 degrees). Further, by noting the distribution of frequencies across the polar zones in the previous categories, the same proportions are used to obtain:

2000 grains Mass Category m Frequency f 30 Polar zones receiving entries = 7 and 11 The frequency in previous = 79 mass category $\overline{m} = 1230$ 11/79 for zone 7 68/79 for zone 11 Distribution of mass in zones 7 and 11 for $\bar{m} = 1230$ Distribution of mass in zones 7 and 11 for m ≈ 2000

Now using σ estimated at 122 for \overline{m} = 2000, we obtain

 $\vec{m} + 0 = 2122$ $\vec{m} - 0 = 1878$

It should be noted at this point that the selection of \overline{m} , σ and consequently $\overline{m} + \sigma$ impose an implied condition of symmetry for the distribution of mass in that particular \overline{m} category. This mass is further apportioned so as to agree with the trend generally defined by the preceding adjacent category thus bending the implied symmetry to conform with a distribution which is most likely not symmetrical. When data is added in this way the recalculated average mass will not generally agree with the original average mass \overline{m} , which was a somewhat arbitrary selection to begin with. The new \overline{m} will be fairly close and in case of the 155 munition the data point was added at 2090 instead of $\overline{m} = 2000$. The completed profile for the new "fictitious" mass category consists of the following:

1. All polar zones empty except 7 and 11

- A mass of 1878 grains with a frequency of 4 is entered in polar zone 7
- A mass of 2122 grains with a frequency of 26 is entered in polar zone 11.

To complete the addition of this new mass category we now consider the conservation of total mass effects. Obviously after the addition of a new mass the total mass T_1 has been increased by some increment T2. Thus, we have from the original or primary data

$$\sum_{i,j} f_{i,j} m_{i,j} = T_1$$
 (34)

where $m_{i,j}$ is the fragment mass in the jth polar zone in the ith mass category, and $f_{i\,i}$ is the associated frequency. Now with the added data points we have

$$\text{FIF } f_{ij} m_{ij} + \text{FIF } f_{ij}^* m_{ij}^* = T_1 + T_2$$
 (35)

where m_{ij}^{\star} and f_{ij}^{\star} are the added data for the additional mass categories \overline{m}_i . The objective is to scale down all f_{ij} , and f_{ij}^{\star} proportionately such that for new f_{ij} ,

$$22 f_{ij}^{m}_{ij} + 77 f_{ij}^{*} m_{ij}^{*} = T.$$
 (36)

Toward this end, let p_{ij} be that proportion of f_{ij} which generate the new f_{ij} such that Eq. (36) is satisfied for new f_{ij} .

Then for original f_{ij},

$$\sum_{i=1}^{k} p_{ij} f_{ij}^{m}_{ij} + \sum_{i=k}^{N} p_{ij} f_{ij}^{*}_{ij}^{*} = T_{1}$$
(37)

Dividing both sides of (37) by $T_1 = \sum \sum f_{ij} m_{ij}$, we have

$$\frac{\sum \sum p_{ij}f_{ij}^{m}_{ij}}{\sum \sum f_{ij}^{m}_{ij}} + \frac{\sum p_{ij}f_{ij}^{*}m_{ij}^{*}}{\sum \sum f_{ij}^{m}_{ij}} = 1$$
 (38)

recalling that $\bar{x} = \frac{\int \int x f(x) g(x)}{\int \int f(x) g(x)}$

the first term in (38) is
$$\overline{p}$$
. Hence,
$$\frac{\sum_{i=k}^{N} p_{ij} f_{ij}^{*} m_{ij}^{*}}{i = 1} = 1$$

$$\sum_{i=1}^{\Sigma_{ij}} f_{ij}^{m} ij = 1$$
(39)

Since the sum $\Sigma\Sigma$ $p_{ij}f_{ij}^{*}m_{ij}^{*}$ is over small ranges of i and j the error will be small if we substitute \overline{p} for p_{ij}

$$\overline{p} + \overline{p} = \frac{\sum \sum f_{ij}^{*}m_{ij}^{*}}{\sum \sum f_{ij}^{m}ij} = 1$$
(40)

or
$$\overline{p} + \overline{p} (T_2/T_1) = 1$$

and

$$\overline{p} = \frac{T_1}{T_1 + T_2} \tag{41}$$

The result shows that we can readjust all the frequencies by one constant of proportionality. Hence, a complete set of new data is generated with an added data point on the cumulative curve with the conservation of mass. The new cumulative curve, plotted from the revised data set, is shown in Fig. 5. As in every other case, the curve is shifted downward, which introduces a conservative element into the interpretation of the data.

B. The 500 lb Bomb

The cumulative distribution for this munition was plotted from the original data and is shown in Fig. 8. Without modification, the original data was divided into ten mass categories:

The problem in this case is poor resolution. The standard deviation for example is 3.26 for category number 4, 8.33 for category number 6, 7.93 for category number 8 and 698.5 for category number 10. It and an addition of 698.5 is not in itself unexpected. Because of 1.3 magnitude, it is an anomaly since its ratio $o/\overline{m} = .754$ is more than ten times the expected value of approximately .06. Moreover, it is a sharp break in the standard deviation trend. If we focus on mass category No. 10, then we find it labeled as 310 +. This is misleading since, in fact, mass category number 10 contains fragments which weigh as much as 5000 grains. To overcome this resolution deficiency, the 10th category was expanded into five additional categories such that the total number of mass categories became 15.

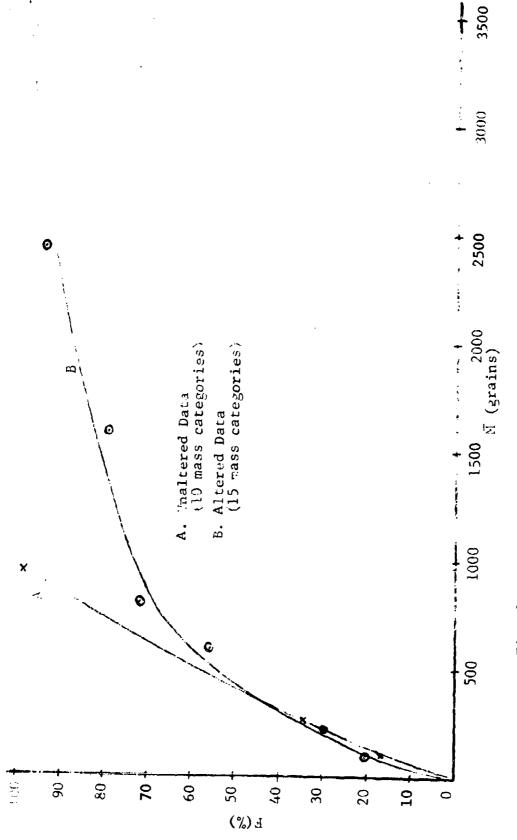

Fig. 8 CUMULATIVE DISTRIBUTION FOR 500 LB BOMB

Category	Range
10	310-450
11	450-750
12	750-1000
13	1000-2000
14	2000-3000
15	3000 +

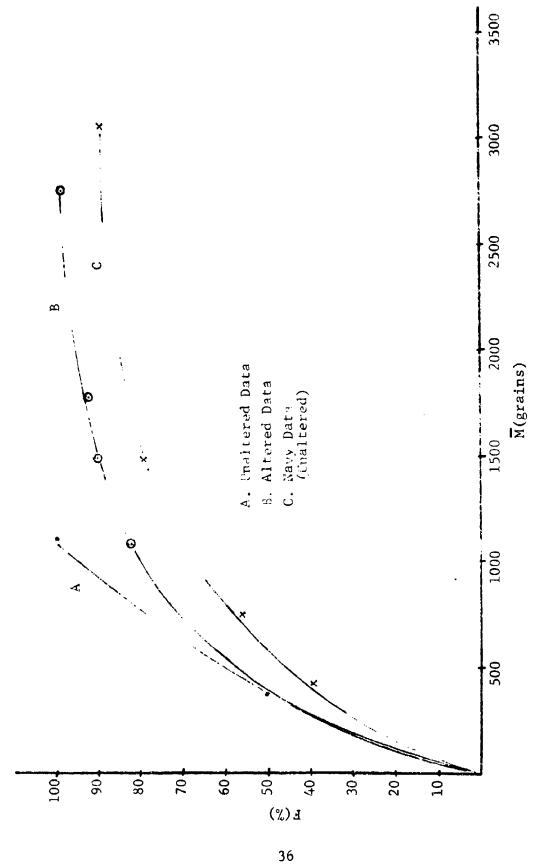

These mass categories were then added on to the data, replacing the former category number 10. The result was a better than 50 percent improvement in the average σ/\overline{m} for categories 10 thru 15 and a smoothing of the expected standard deviation trend. The altered cumulative distribution is shown in Fig. 8.

The data received from the Navy was not directly usable with out extensive recoding and key punching. This was done for the 750 lb bomb and the cumulative distribution appears in Fig. 9. This curve falls below the curves for the original data and its altered form. Since the lower curve implies more mass in the higher mass categories it also implies a greater damage influence range. In all cases the alteration of the data produced the same effect by lowering the cumulative distribution curve.

The following is a summary of how the remaining data were altered. No alterations were necessary for the 105 mm shell.

750 1b bomb: originally had 12 categories. The label on category 12 was 450+. Six additional categories were added as follows:

- 12 450-700
- 13 700-900
- 14 900-1200
- 15 1200-1500
- 16 1500-2000
- 17 2000-3000
- 18 3000 +

CIMULATIVE DISTRIBUTION FOR 750 LB BOMB Fig. 9

The cumulative distribution is shown in Fig. 9

5 inch Munition: 11 mass

categories were expanded to 14 as follows:

- 11 250-450
- 12 450~700
- 13 700-1500
- 14 1500-2000

The cumulative distribution is shown in Fig. 10.

The 8 inch Munition: 10 mass

categories were expanded to 16 as follows:

- 10 160-300
- 11 300-500
- 12 500-700
- 13 700-1000
- 14 1000-2000
- 15 2000-3000
- 16 3000+

The cumulative distribution is shown in Fig. 11.

The 175 mm munition: two data points were added to the cumulative distribution as shown in Fig. 12. The technique was the same as described for the 155 mm munition.

A complete set of the revised munition effectiveness tables are presented in Appendix E to this report. Their format is similar to that shown in Table 1.

3.3 Model Sensitivity to Input Data

In order to gain an appreciation for the sensitivity of the fragment hazard model output to alteration of munition effectiveness data, which is input to the model, a computational experiment was conducted. The unaltered and altered data sets for the 175 mm gun shell were used as input to the model. The results of these two cases are shown respectively in Figs. 13 and 14. The primary difference between the two sets of contours is the location of the lowest value contour line.

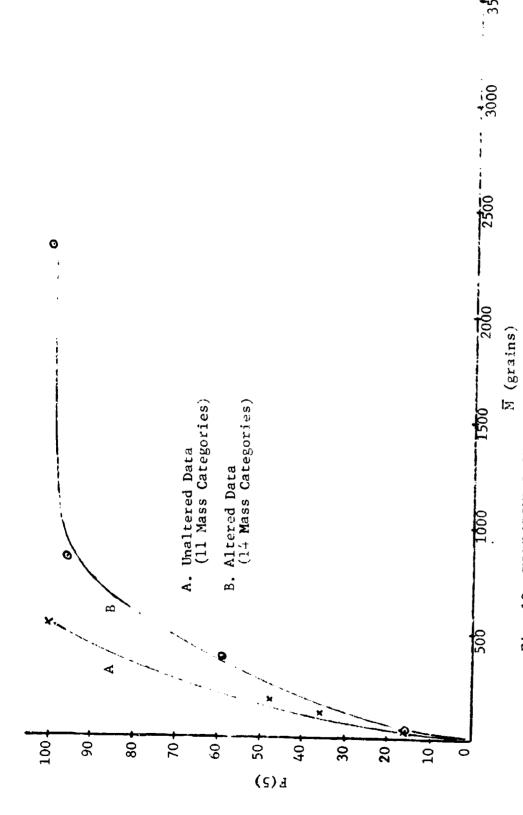

Fig. 10 CUMULATIVE DISTRIBUTION OF PASS FOR THE 5 IN. MUNITIONS

ŝ

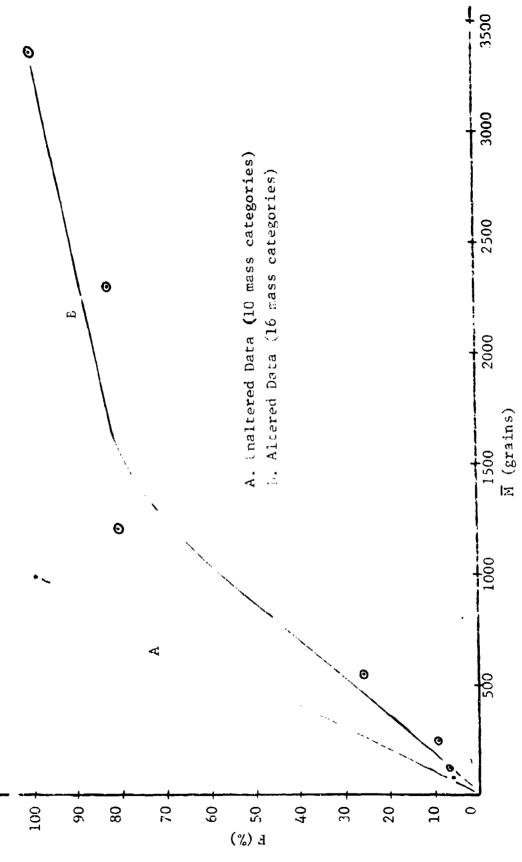

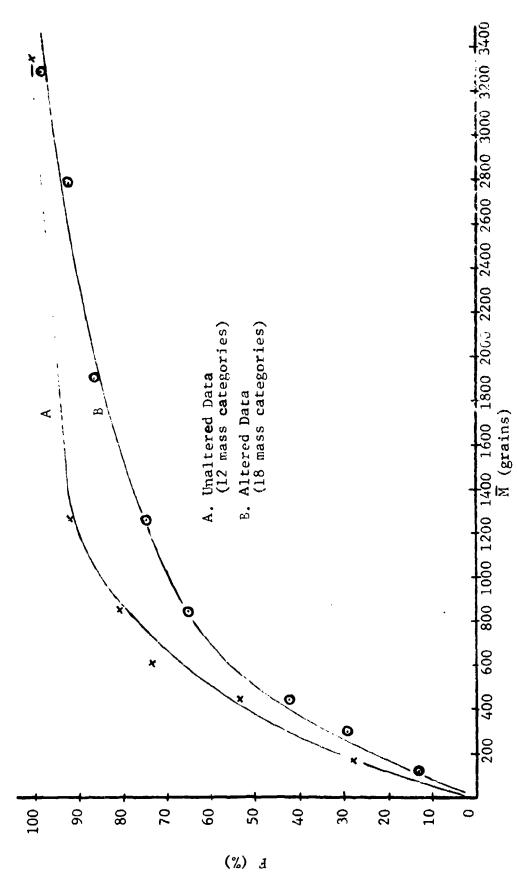

Fig. 11 CONTAILVE DISTRIBUTIONS OF MASS FOR THE 8 IN. MUNITIONS

CUMULATIVE DISTRIBUTION OF MASS FOR THE 175 MM MURITIONS Fig. 12

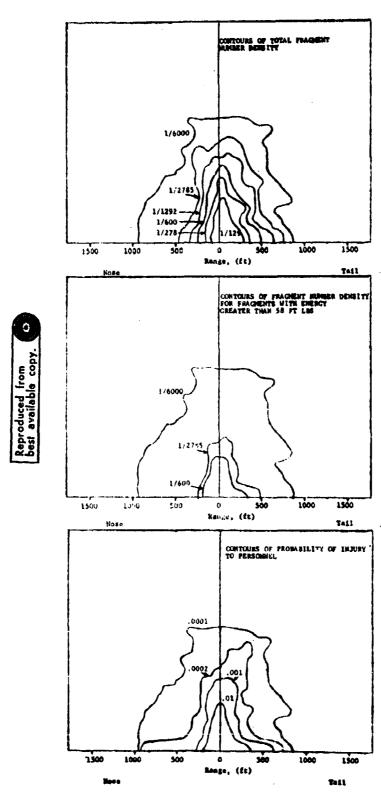

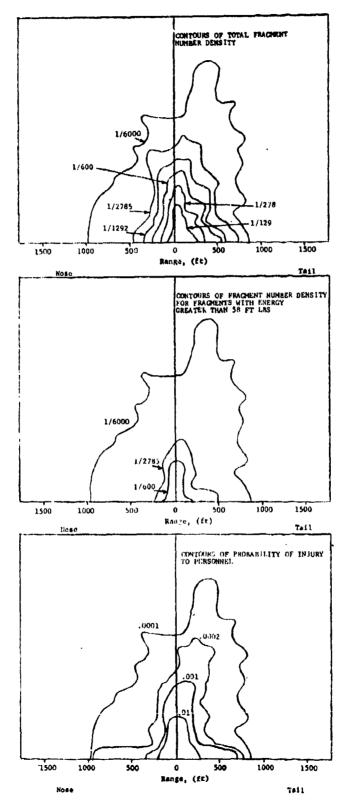

Fig. 13 175 MM GUN SHELL M437A2 (COMP. B LOAD) (UNALTERED DATA)

Fig, 14 175 MM GUN SHELL M437A2 (COMP. B LOAD) (ALTERED DATA)

The altered dara set represents an emphasis on the resolution of the heavier fragments, (e.g., note Fig. 12) at the expense of lower weight fragments. This has the pronounced effect of shifting the location of the lowest value contour line outward for the altered data set. In terms of safety, then, the altered data set results in a more conservative set of contours.

4. RESULTS, CONCLUSIONS, AND RECOMMENDATIONS

This study has resulted in the development of a computer model which generates the information necessary in establishing minimum separation distances between various munition types and personnel in order to mitigate fragment hazards. The model specifically treats the fragment hazard associated with a single munition and has been utilized to generate single unit fragment hazard data for seven common military munitions. While single unit detonation does not represent a realistically severe accident situation, previous work indicates that multiple unit (i.e., stacks) fragment hazards may be proportional to single unit results. If this is true, and there is evidence to support such a hypothesis in the case of thin wall munitions, then the results obtained herein are directly applicable to estimating the fragment hazards associated with openly stored munitions.

4.1 Results

- Contour maps, expressing number density and injury probabilities (i.e., Appendix B), are seen to be particularly pronounced in three fixed sectors of the ground plane; that is, the nose, tail and sidespray sectors. Average values within each of these sectors have been expressed as functions of the radial distance from the explosive source. (i.e., Appendix C)
- Examination of the relationships in Appendix C indicate that the side spray sector is the critical area in the case of thick wall "shell type" munitions and to a limited degree in the thin wall "bomb" munitions.
- The curves in Appendix C also serve to illustrate how the kinetic energy criterion for personnel injury (i.e., 58 ft-lbs) reduces the applicable number density. At a given range the number density is reduced as much as an order of magnitude. It should be recognized that consideration of a less severe kinetic energy criterion will lead to lesser reduction in number density and thus a more conservative injury criterion in terms of safety.
- Table 4 summarizes the results available in Appendix C for each of the seven munitions considered. The table gives the computed distances corresponding to a fragment density of one hit in 600 ft² for all fragments and fragments with a terminal energy in excess of 58 ft lbs.

TABLE 4

SUMMARY TABLE FOR THREE PRINCIPAL DIRECTIONS AT 1 HIT PER 600 SQ FT (ENTRIES ARE IN RADIAL FEET)

4.2 Conclusions

- By utilizing trajectory analysis in conjunction with stochastic treatment of experimental input data and damage functions, a mathematical model has been developed for estimating injury/damage contours for various single unit munitions.
- The mathematical model currently utilizes published munition effectiveness data which has been altered to give more emphasis to heavier fragments. It has been observed that this results in extending contour levels outward giving a more conservative result insofar as fragment safety is concerned.

4.3 Recommendations

Before making specific recommendations concerning the results generated in this study and future research efforts it is prudent to discuss the adequacy of munition effectiveness data as input to the model.

The results generated by the computer model are dependent upon and quite sensitive to the munition effectiveness data, which is input. This data was originally generated to support munition effectiveness studies and is the result of explosive tests of single unit munitions. It is the only known source of information concerning near-field estimates of munition fragment size, number and initial velocity. However, since it has been collected to be utilized in weapon effectiveness studies, it is primarily concerned with the fragments which are effective within the applicable range of the munition. This has normally led to a set of data which has a high degree of resolution, in terms of weight intervals, where the greatest number of fragments are concentrated. This unfortunately is at a rather low fragment weight (e.g., below 300 grains). The remaining fragment weight of the munition is quite substantial, but because it does not break down into very many fragments and is not always projected into the designed zones of munition effectiveness, its recorded resolution is usually quite poor.

Another inadequacy of recorded munition effectiveness data is concerned with its use in representing the basis for multiple unit munitions fragment hazard analysis. Here, the primary concern is whether the munition fragment size, number and initial velocities will be similar for munitions in single and multiple units.

In the present study an attempt has been made to overcome the first of these deficiencies in a conservative manner. That is, existing munition effectiveness data have been altered to adequately resolve higher weight fragments in a statistical sense. Recently reduced data, developed at the Naval Weapons Laboratory, tend to support these alterations; however, the best way to resolve this problem would be the design and use of an experimental procedure aimed at obtaining arena data for hazard analysis.

The problem in assuming similar fragment characteristics for multiple and single unit stacks is a much more difficult problem to resolve. A number of detonation tests of stacked munitions have been conducted in the past where resulting fragments have been collected. In some cases the fragments have also been sized and number and weight distributions computed. Results of these studies indicate that thinwall "bomb type" munitions tend to fragment into similar size fragments for both multiple and single units. However, it is becoming quite apparent that this is not the case for thickwall "shell type" munitions. Here, fragment weight and number distributions from multiple units are quite different from single unit munitions.

In light of the input deficiencies enumerated above, the following recommendations are made:

- To take care in utilizing results obtained in this study for single unit munitions, in projecting fragment hazards associated with multiple units of similar munitions. This is especially true of "shell type" munitions.
- To compare the analytic results for the single unit 750 lb bomb obtained in the present study with experimental multiple unit results obtained in the NWC-China Lake Tests of March, 1970. Such a comparison will serve to validate our analytic procedures and the extension of our results for estimating multiple unit "bomb" fragment hazards.

• To characterize the resulting fragment number and weight distributions obtained from the June, 1970 155 mm shell tests at Yuma and the corresponding 155 mm shell tests at China Lake in December of 1971. These tests are expected to be dissimilar amongst both themselves and as compared to single unit results. However, such comparison will document these differences and the resulting distributions can be utilized by the analytic model to estimate the fragment hazard associated with both these cases.

APPENDIX A

PROGRAM USER'S MANUAL

APPENDIX A PROGRAM USER'S MANUAL

The computer program for the fragment hazard model has been written in such a manner as to accept a problem-oriented input language. The following discussion describes, in detail, the various control and data statements required to execute the program. An example of the use of these statements in a sample problem is included.

Control Cards

All control cards start with column 1 = '\$'. The remainder of the card is free format. Only columns 1-72 may be used for control text; columns 73-80 are not examined and may be used for anything.

Control Statement Form

Control statements are of the form:

name field1 field2 ... fieldn

where 'name' identifies the control statement, and the 'field's are parameters whose form depend on the particular control statement. 'name' and the 'field's are separated from one another by

- 1) one or more blanks, or
- 2) a comma, padded on either side by one or more blanks. Examples: \$PRINT CON, DATA

\$TAPE 4,SRCH=01100,BKSP

\$STOP

If desired, comments preceded by a '\$' may appear after the last field.

Example: \$STOP \$ END OF RUN

If a control statement will not all fit on one card, it may be continued to additional cards in the following way:

1) place a comma after the last field on the first card.

- 2) start the second card with a '\$' and a ',' (padding with blanks if desired).
- 3) place remaining fields after the '\$' and ',' on the second card.
- 4) as many continuation cards as necessary may be used.

Example: \$ORDNANCE FORMAT=2, REDUCE, REZONE, NORM, SMOOTH, \$, READ=3, LIST \$ READ FROM TAPE 3

Parameter Form

Control statement parameters may be of three forms:

1) Positional: A value which must appear in its proper order on a control statement, as the first parameter, third parameter, etc.

Examples: 3, 14.197, T, 'TITLE A'

2) Flag: A name, or the two characters 'NO' prefixed to a name. A flag may appear anywhere in a control statement after the positional parameters (if any). A flag is associated with a logical value: this value is TRUE if the flag's name is specified, or FALSE if 'NO' plus the flag's name is specified.

Examples: LIST, NOLIST, BCD, BIN

3) Keyword: A name, followed by either a BCD (3-8 punch) or an EBCDIC (6-8 punch) equal sign (=), which may be padded with blanks, followed by a value.

A keyword parameter may appear anywhere in a control statement after the positional parameters (if any).

The variable represented by the name is set to the provided value.

Examples: ORDER=2, Z=5.5, FLAGS=XY, TITLE='TITLE A'

Value Form

There are four types of values:

1) Logical: a string of one or more characters, not containing any of the following: dollar sign (\$), comma (,), equal sign (=), blank, or apostrophe ('). If a T appears in the string before an F appears, the value is TRUE. If an F appears before a T appears, or if neither an F nor a T appear, then the value is false.

Examples: T, .TRUE., TRUFFLE and TRUE are all TRUE. F, .FALSE., AFTER, FALSE and NO are all FALSE.

2) Integer: one or more digits, optionally preceded by a + or - sign.

Examples: 0, -1234, +77111

3) Real: a real number. Decimal point and exponent may be used. The exponent, if present, must be of one of the following forms:

En, E+n, E-n, +n, -n where n is one or two digits.

Examples: 0, -1234, +77111, 3.1416, 6.0238E+23, 1.-5, -.1+10, 51E6

- 4) Alphabetic: two forms are allowed.
 - a string of one or more characters, not containing any of the following: dollar sign (\$), comma (,), equal sign (=), blank or apostrophe (').

Examples: ABC, 123, MACH-1

• a string of zero or more arbitrary characters, enclosed in apostrophes ('). Within the string, one apostrophe is represented by a pair of apostrophes. Either the BCD (4-3 punch) or EBCDIC (5-8 punch) apostrophe may be used.

Examples: 'ARTHUR', 'WHICH WAY?', 'DON''T GO', 'TITLE A', '' (a null string)

Notation

When describing control cards, some possibly unfamiliar notation is used. This can be explained with an example:

\$TAPE $n \left\{ \begin{array}{l} BCD \\ BIN \end{array} \right\} [, REW]$

The use of { } means that only one of the arguments listed may be used. If one of the arguments is underlined, that one will be assumed if none of the group are specified. (In the example, BIN is assumed unless BCD is used. BIN and BCD may not both be used.) The use of [] means that the enclosed argument is not required; it may be used or not used.

\$PRINT [,CON][,DATA]

Print controls

CON Cause control cards to be printed.

DATA Cause data cards to be printed

\$STOP

End of run; execution is terminated.

\$TIME

Print elapsed time since beginning of execution, and since last \$TIME statement.

STAPE $n = \begin{cases} BCD \\ BIN \end{cases}$ [, REW][, SKIP=k] $\begin{cases} SRCH=\alpha \\ XSRCH=\alpha \end{cases}$, BKSP][, WEOF]

Tape file manipulations. If more than one of the operations (REW through WEOF) are specified, the operations take place in the order REW, SKIP, SRCH or SXRCH, BKSP, WEOF, regardless of the order in which the operations are specified.

n Tape unit number

BCD Tape is formatted (BCD)

BIN Tape is unformatted (binary).

If neither BCD nor BIN is specified, BIN is assumed.

REW Rewind unit n.

SKIP=k Skip k records on unit n.

SRCH= α Search unit n, starting at its present position, for a sentinel record whose key is α (1 to 8 characters). Terminate if no such sentinel is found before the end-of-file.

XSRCH=\alpha Proceed as with SRCH, but if an end-of-file is encountered, rewind unit n and search the entire file. Terminate if end-of-file is again reached without finding the proper sentinel.

BKSP Backspace unit n one record.

WEOF Write a terminal sentinal record and an end-of-file mark on unit n.

\$ORDNANCE FORMAT=n[,NSETS=n][,REDUCE][,REZONE][,NORM][,SMOOTH]

[,ORDER=n][,READ=n][,LIST][,KWIKPLOT][,SUMMARY]

Cause a title card and a set of ordnance data to be read.

FORMAT=n Ordnance format code. =1 or 2.

NSETS=n Number of ordnance components (fuz., casing, etc.) If ≤ 0 or omitted, NSETS=1 is assumed.

REDUCE Halve the number of mass categories by combining each pair of categories.

REZONE Transform data from N+1 sets of values at the boundaries of N polar zones to N sets of values at the N polar zone midpoints.

NORM Normalize data, given as total number of fragments per mass category per polar zone, to number per unit area on a unit sphere surrounding the ordnance.

SMOOTH Fill in gaps in data, and (if ORDER>0) apply a smoothing function to the ordnance data.

ORDER=n Use an nth order Fourier series to smooth data (if SMOOTH is specified).

READ=n Read ordnance data from unit n, a BCD card image unit. If n=5 or if READ=n is omitted, ordnance data is assumed to follow the \$ORDNANCE statement.

LIST List ordnance data in tabular form.

SUMMARY List data summary information: total mass per mass category, per polar zone, etc.

KWIKPLOT Produce printer plots of velocity curve, and of mass and number curves for each mass category, all as a function of polar angle.

An ordnance title card is read immediately after a \$ORDNANCE statement is encountered. Columns 1-72 contain a description of the ordnance.

Two basic formats are defined for ordnance data (FORMAT=1 and 2). Within the context of each format, several data conditioning options are available (REDUCE, REZONE, NORM, SMOOTH, ORDER=n).

Ordnance data is read from cards if the READ field is omitted, or if READ=5. If a READ field specifies some other I/O unit, input is read from that unit in card image form. This unit is assumed to be properly positioned.

The first card (or card image) of a set of ordnance data is as follows, regardless of the type of ordnance data.

COLS	FORMAT	NAME	DESCRIPTION
1-5	15	NMORI)	Number of mass categories. If NMORD> 30 (maximum number of mass
			categories), REDUCE must be specified to cut the number of mass categories in half.
6-10	15	NVORD	Number of measurement positions along a meridian from nose to tail. Measurements may be made either at the center or at the edges of equi-spaced polar zones. In the latter case, REZONE must be specified NVORD 37.
11-15	ي 5	IDORD	Ordnance f.D. number 0≰IDORD <u>⊀</u> 99.
16			(ignored)
17	Al	IVO	Ordnance modification code. If left blank, IVO='0' is assumed.
18-20			(ignored)
21-30	E10.0	XKORD	Average fragment drag factor (grains/in.3

Format 1 Ordnance Data

Data of format 1 consists of NVORD groups of cards, each containing:

- [NMORD/4]* cards, in (4(2F5.1,5X))format, containing NMORD pairs of values: the average fragment mass (grains) and the average number of fragments for each mass category, for one polar zone.
- one card, in (50X,E10.1) format, containing the average fragment initial velocity (fps) for one polar zone.

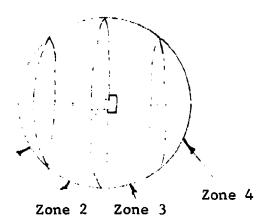

Format 2 Ordnance Data

Data of format 2 is split into two parts.

Part 1 contains NSETS of cards, each consisting of [NMORD/4] groups of NVORD cards. Each card is in (8E10.0) format and contains four pairs of values: the average fragment mass (grains) and the average number of fragments for four mass categories, for one polar zone.

 $[\]frac{*}{[X]}$ means the smallest integer not less than X. Examples: [3.14]=4, [14]=14, [7.00001]=[7.9999]=8.

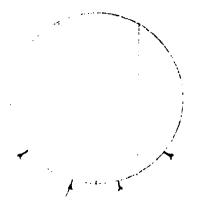

^{**}Fragment number information in the form of a count of the total number of fragments in a polar zone may be used, provided that the NORM parameter is specified on the \$ORDNANCE statement.

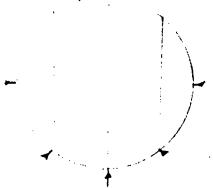

Hypothetical Sphere of Unit Radius Surrounding Ordnance.

Zone 1

Sphere divided into four polar zones, each of equal latitude range.

Measurements Taken at Center of Zones

Measurements Taken at Zone Boundaries (REZONE Parameter Required on \$ORDNANCE Statement)

Part 2 contains NSETS sets of cards, each consisting of NVORD cards in (50X,E10.0) format, each of which contains the average fragment initial velocity (fps) for one polar zone.

\$BOOM [,FLAGS=\alpha][,NBAR=n][,ORDER=n][,Z=h][,DRNG=r][,NRNG=n]
[,NEL=n][,NAX=n]

Generate a fragment distribution using ordnance data read according to the prior \$ORDNANCE statement. Write the fragment distribution field, with a sentinel record on binary unit 4.

FLAGS= α consists of one or two characters. If α is one character, the second flag character is assumed to be zero. If the FLAGS field is omitted, both flag characters are assumed to be zero. The flag characters are used in the sentinel I.D. for the fragment field output.

NBAR=n Number of barriers placed in the vicinity of the ordnance. If omitted, NBAR=0 is assumed. Barrier description cards, if any, are read after the fragment field title card, NBAR≤1.

Z=h height of target plane (in feet) above ordnance. If Z**<**0, the ordnance is above the target plane.

DRNG=r spacing of range points, in feet.

NRNG=n number of range points on an azimuth ray, NRNG ≤ 20 .

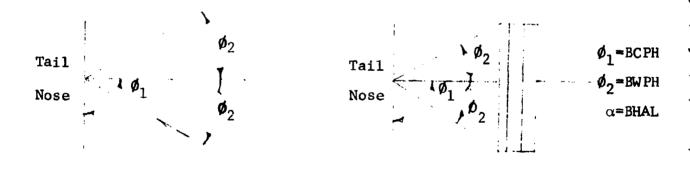

NEL=n Number of elevation angles to be considered (high register fragments), NEL ≤ 18.

NAZ=n number of azimuth rays in fragment field (a semi-circle), NAZ≤36.

The following cards are read immediately after a \$BOOM statement is encountered:

- A title card. Columns 1-72 contain a description of the fragment field.
- If NBAR, NBAR barrier description cards are read. The format of each card is:

COLS	FORMAT	NAME	DESCRIPTION
1-5	15	13TYP	Barrier type code. l=barrier is a circular arc, with ordnance at center. 2=barrier is straight and is closest to the ordnance at its midpoint.
5-10			(ignored)
11-20	E10.0	всрн	Azimuth angle (deg) of barrier midpoint
21-30	E10.0	BWPH	Extent of barrier in azimuth (deg) on either side of midpoint.
31-40	E10.0	BHAL	Angular height of barrier (deg), as seen from the ordnance. If IBTYP=2, this angular height is measured at the midpoint of the barrier.

\$OUTPUT {
,TABLES
,PARAMS
,LIMITS
,EXEC[,PLOT][,KWIKPLOT]
,RANGE
,SOJAC
,TABLES
,LIMITS
,LIMITS
,EXEC[,PLOT][,KWIKPLOT]

Read function definitions or compute and plot functions of the fragment field variables (velocity, striking angle, and number per square foot, as functions of range and azimuth).

The fragment field is read from binary unit 4, which is presumed to be properly positioned.

TA BLES

Read Damage Threshold Velocity Tables or Formula Coefficients.

Between two (2) and five (5) cards are read for each Table or Formula. The formats of these cards are given below. The end of input is marked by a card containing blanks or zeroes in columns 1 and 2.

PARAMS

Read a title card, and fragment threshold and target description cards for each fragment field function.

Between two (2) and four (4) cards are read for each function. The formats of these cards are given below. The end of input is marked by a card containing blanks or zeroes in columns 1 and 2.

LIMITS

Read an output parameter card for each fragment field function.

The format of this card is given below. The end of input is marked by a card containing blanks or zeroes in columns 1 and 2.

^{*}The formula used is the empirical relationship derived under project THOR.

EXEC

Compute and plot specified functions of a previously computed fragment field. Functions are specified on the data card following this control card. The format of this card is given below.

The fragment field is read from binary unit 4, which is presumed to be properly positioned.

The functions are specified using two digit codes, whose meanings are:

- 01 total number of fragments (per sq ft)
- 02 total fragment mass (1b)
- 03 total fragment momentum (lb-sec/ft²)
- 04 total fragment kinetic energy (ft-1b/ft²)
- 05-07 (unused)
- 08* average fragment impact velocity (ft/sec)
- 09* average fragment impact angle (radians)
- lj number of damaging fragments,
 using table j.
- 2j probability of damage, using table j.
- 3j compute and plot 1j and 2j together
 (this is cheaper than specifying lj
 and 2j separately)
- 4j number of damaging fragments, using Thor coefficient set j.
- 5j probability of damage, using Thor coefficient set j.
- 6j compute plot 4j and 5j together (this is cheaper than specifying 4j and 5j separately)

7j-9j (unused)

Up to eight (8) functions may be computed and plotted at one time. To plot more than eight functions, the fragment field file must be repositioned, and another set of plots requested.

^{*}Functions 08 and 09 must both be specified if either is, and must be the last function codes specified.

Note that a function code of 3j or 6j causes two plots to be generated, and that specification of functions 08 and 09 counts for 3 functions, even though only two plots are generated.

PLOT cause function values to be written to the plot file (file 2) for later processing by a contour plotting program.

KWIKPLOT generate contour plots of functions values on the printer.

RANGE read plot range parameters from data card following this control card. The format of this card is given below.

SOJAC read characters to be used for printer plotter (see KWIKPLOT) from data card following this control card. The format of this card is given below.

LIST list data read with this control card.

Data cards read after a \$OUTPUT, TABLES statement. Between two and five cards are read for each table or formula coefficient group.

3 1

COLS	FORMAT	NAME	DESCRIPTION
Heading	Card		
1	11	IT	type code. If IT=1,2 or 3, table IS is to be read. If IT=4,5 or 6, coefficient group IS is to be read.
			IF IT=0 and IS=0, the end of this group of data cards has been reached.
2	11	IS	table or coefficient group number. 0 <is-9.< td=""></is-9.<>
3-5			(ignored)
6-10	15	NTB	(used only for tables) number of M-V pairs to be read. NTB<14.
11-15	15	JDUM	(used only for tables) interpolation mode. All table values are read in true form, but linear interpolation of the table during processing may require either a log or linear scale, according to JDUM: =00 M linear, V linear =01 M linear, V log =10 M log, V linear =11 M log, V log

<u>Coefficients</u> (formula coefficients only)

1-70 7E10.0 (COEF(1), I=1,7) - Thor formula coefficients, group 1S.

Fragment Mass Values (tables only)

NTE masses are read, 7 per card.

1-70 7E10.0 (XTB(I), l=1,7) - Fragment mass values, (grains) for table IS.

Damage Threshold Velocity Values (tables only)

NTB velocities are read, 7 per card.

1-70 7E10.0 (YTB(I), I=1,7) - Damage threshold velocities (ft/sec) for table IS.

Data cards read after a \$OUTPUT, PARAMS statement. Between two and four cards are read for each fragment field function.

COLS.	FORMAT	NAME	DESCRIPTION		
Heading	Card				
1	11	IT	Function type. If IT=0 and IS=0, the end of this group of data cards has been reached. If IT=0 and IS>0, then the function requires neither a table nor a Thor formula, and the function type is given by IS. IF IT>0, then IT determines the function type.		
			 number of damaging fragments per sq ft, using table IS. probability of damage, using table IS. number of damaging fragments per sq ft using coefficient set IS in the Thor formula. probability of damage using coefficient set IS in the Thor formula. 		
2	11	IS	table number (if IT=1 or 2), coefficient group number (if IT=4 or 5), or function type (if IT=0):		
·			<pre>=1 total number of fragments per sq ft =2 total fragment mass (1b) per sq ft =3 total fragment momentum (1b-sec) per sq ft =4 total fragment kinetic energy (ft-lb) per sq ft =8 average fragment impact velocity (ft/sec) =9 average fragment impact angle (radians)</pre>		
3			(ignored)		
4	A1	IVP	Function variant code. A blank is treated as a 'zero' character. IVP is used to distinguish plots of the same function, but with different parameters.		
5			(ignored)		
6-10	15	NF	Number of parameters (0 <nf<14) are="" if="" nf<14,="" not="" parameters="" read="" set="" td="" to="" zero.<=""></nf<14)>		

COLS. FORMAT NAME DESCRIPTION

Title Card

1-72 12A6 (ITTLF(I), I=1,12) - function title, which will appear on all plots of this function.

Parameter Card(s)

NF parameters are read, 7 per card. If NF=0, no cards are read.

1-70 7E10.0 (F(I), I=1,NF) - parameters affecting function performance.

Parameters 1 through 7 have the same meaning for all functions:

- F(1) miminum fragment weight (grams). All lighter fragments are ignored.
- F(2) minimum fragment velocity (ft/sec). All slower fragments are ignored.
- F(3) minimum fragment momentum (1b-sec). All fragments whose momentum is too small are ignored.
- F(4) minimum fragment kinetic energy (ft-1b). All fragments whose kinetic energy is too small are ignored.
- F(5) F(7) (reserved)

Parameters 8 through 14 are used only if IT>0.

- F(8) target plan area (ft²)
- F(9) average target elevation area (ft²)
- F(10) F(11) are used only if IT=4 or 5.
- F(10) target thickness (in.)
- F(11) target hardness, where applicable.
- F(12) F(14) (reserved)

Data cards read after a \$OUTPUT,LIMITS statement. One card is read for each function.

COLS.	FORMAT	NAME	DESCRIPTION
1	11	IT	Function code (see PARAMS discussion above)
2	12	IS	subcode or table code (see PARAMS discussion above)
			Note that if IT=0 and IS=0 the end of this group of data cards has been reached.
3-10			(unused)
11-14	14	ISM	Plot smoothing code. IF ISM=0, do no smoothing. IF ISM=1 to 5, smooth by replacing each value by the average of the values in a 2*ISM+1 raster square centered on that value.
15	11	ISC	Plot scale code. ISC=0 to request a linear plot. ISC=1 to request a plot of the log of the function.
16-20			(unused)
21-30	E10.0	OZMIN	minimum value to be plotted.
31-40	E10.0	OZMAX	maximum value to be plotted. If OZMIN>OZMAX, the plot range is set internally.

COLS. FORMAT NAME DESCRIPTION

Data card read after \$OUTPUT, EXEC statement. See discussion of the EXEC parameter for the list of valid function codes.

1-2 I2 first function code

3-5 (ignored)

Subsequent function codes go in columns 6-7, 11-12, etc.

Data card read after \$OUTPUT, SOJAC statement.

1-5			(ignored)
6-10	15	NZ	number of function value ranges to be plotted on printer. $NZ \leq 50$
11-19			(ignored, leave blank)
20-69	50A1	(CH(I),	,I=1,NZ) - plot characters for each function value range.

Data card read after \$OUTPUT, RANGE statement.

1-5			(ignored)
6-10	15	NX	number of resolution increments in X direction (tail to nose). $NX \leq 81$.
11-15	15	NY	number of resolution increments in Y direction (laterally from waist of munition). Normally NY=(NX-1)/2+1. NX<41.
16-20			(unused)
2130	E10.0	XMIN	minimum X value (ft)
31-40	E10.0	YMIN	minimum Y value (ft). Normally YMIN=0.
41-50	E10.0	DX	X increment (ft). Normally NX,XMIN and DX are set so that XMAX=-XMIN where XMAX is XMIN+DX*(NX-1).
51-60	E10.0	DY	Y increment (ft). Normally NY and DY are set so that YMAX=XMAX where YMAX is DY*(NY-1) if YMIN=0.

Sample Data Deck

the deck listed on the next page is set up to do the following job:

- 1) Read munition data for munition No. 4 (mod 1). Gaps in the data are to be filled in, and the data is to be listed neatly in tabular form.
- 2) A fragment field is to be computed, on a polar grid consisting of 8 ranges spaced 250 feet apart, and 18 azimuth rays, spread evenly over a half-circle (at azimuths 5, 15, ..., 175 deg). After the fragment field has been written onto tape 4, an end of file is written and the tape is rewound.
- 3) Output specifications are read. These include
 - a. the printer-plotter character set,
 - b. the size and resolution of the plot,
 - c. the trivial (0-velocity) fragment threshold velocity table,
 - d. the function limits and scale (all are to be plotted in log units), and
 - e. the function titles and parameters.
- 4) Plots are generated. The function specifications 01 and 30 cause functions 01, 10 and 20 to be generated and plotted.

Sentinel Records

The munition data file (if one is used), the fragment field file, and the output function file (if one is used) each consist of several groups of data. Each group is preceded by a sentinel record which identifies the group, as described in the following section. In addition a special sentinel record is written after the last data group.

A sentinel record exists in two forms, one for formatted files (the BCD munition data file), and one for unformatted files (the binary fragment field file and the binary output function file).

Formatted sentinel record:

char. 1-6 '*HEAD*'

char. 7-14 an 8-character search key. (If fewer than 8 characters, blanks are added.)

Search for a formatted data group using the statement:

\$TAPE n,BCD,SRCH=key,BKSP

Unformatted sentinel record:

word 1 '*HEAD*'

word 2** an 8-character search key. (If fewer than 8 characters, blanks are added.)

Search for an unformatted data group using the statement:

\$TAPE n, SRCH=key, BKSP

^{*}Two words are needed when using a computer with four characters per word.

Two words are needed when using a computer with four or six characters per word.

Sentinel Record Keys

1. A 3-character key of the form

XXI

is used for munition data. (BCD tape)

XX = munition ID number. 00<XX<99

 $I = a \mod ification code$. Normally I=0.

2. A 5-character key of the form

XXIJK

is used for fragment field tables. (Binary tape 4)

XX,I as above

3. An 8-character key of the form

XXIJKYYL

is used for output function tables. (Binary tape 2)

XX,I,J,K as above

YY = output function code. (See \$OUTPUT discussion.)

L = output function modification code(to reflect changes in threshold or target parameters, etc.).

Normally L=0.

4. The sentinel record which should end a file has an 8-character key which is

9999999

A sentinel record may be written with the statement

\$TAPE n[,BCD],WEOF

Timing

The generation of the fragment field is the most time consuming part of the program. Several parameters affect timing in this phase.

NM number of mass categories into which munition data is divided

NAZ number of azimuth angles

NEL number of elevation angles

DRNG range increment (ft)

 Δ 11 operations are performed for each mass category at each azimuth. Low-register fragment trajectories are computed for ranges R_i =DRNG*i, out to R_i = R_{max} , which corresponds to an initial elevation angle of α_{max} . High-register fragment trajectories are computed for elevations α_i =(i-1/2) $\Delta\alpha$, where $\Delta\alpha$ =90°/NEL, and where α_{max} < α_i <90° holds.

Thus the computation time for low register fragment trajectories increases as DRNG decreases, and the computation time for high register fragment trajectories increases as NEL increases. So the expected computation time is given by

T=A*NM*NAZ*(1+B/DRNG+C*NEL)

Because all runs done for this project used the same values of NAZ, DRNG and NEL, the constants A, B and C cannot be determined at this time. However, the approximate relation (in sec)

 $T=7 \times NM$

and has been observed on the Univac 1108, with NAX=18, DRNG=250 and NEL=18.
